LETTER

Equilibrium and non-equilibrium dynamics simultaneously operate in the Galápagos islands

Abstract

Island biotas emerge from the interplay between colonisation, speciation and extinction and are often the scene of spectacular adaptive radiations. A common assumption is that insular diversity is at a dynamic equilibrium, but for remote islands, such as Hawaii or Galápagos, this idea

Luis M. Valente,^{1*} Albert B. Phillimore² and Rampal S. Etienne³

DAISIE

“Here, we develop DAISIE (Dynamic Assembly of Islands through Speciation, Immigration and Extinction), a likelihood-based phylogenetic method that unifies the island biogeography framework of MacArthur & Wilson with the phylogenetic birth-death models popularised by Nee et al.”

λ^c μ K γ λ^a

DAISIE unifies
island biogeography
with
birth-death models

DAISIE

Description

μ

Per-species extinction rate

γ

Per-species immigration rate

λ^c

Per-species cladogenesis rate

λ^a

Per-species anagenesis rate

K

Carrying capacity

λ^c

DAISIE unifies
island biogeography
with
birth-death models

Figure 1

25 species, 8 clades

Figure 2

“According to the most strongly supported DAISIE model, the avifauna of the Galapagos islands does not tend towards a diversity steady state”

Figure 3

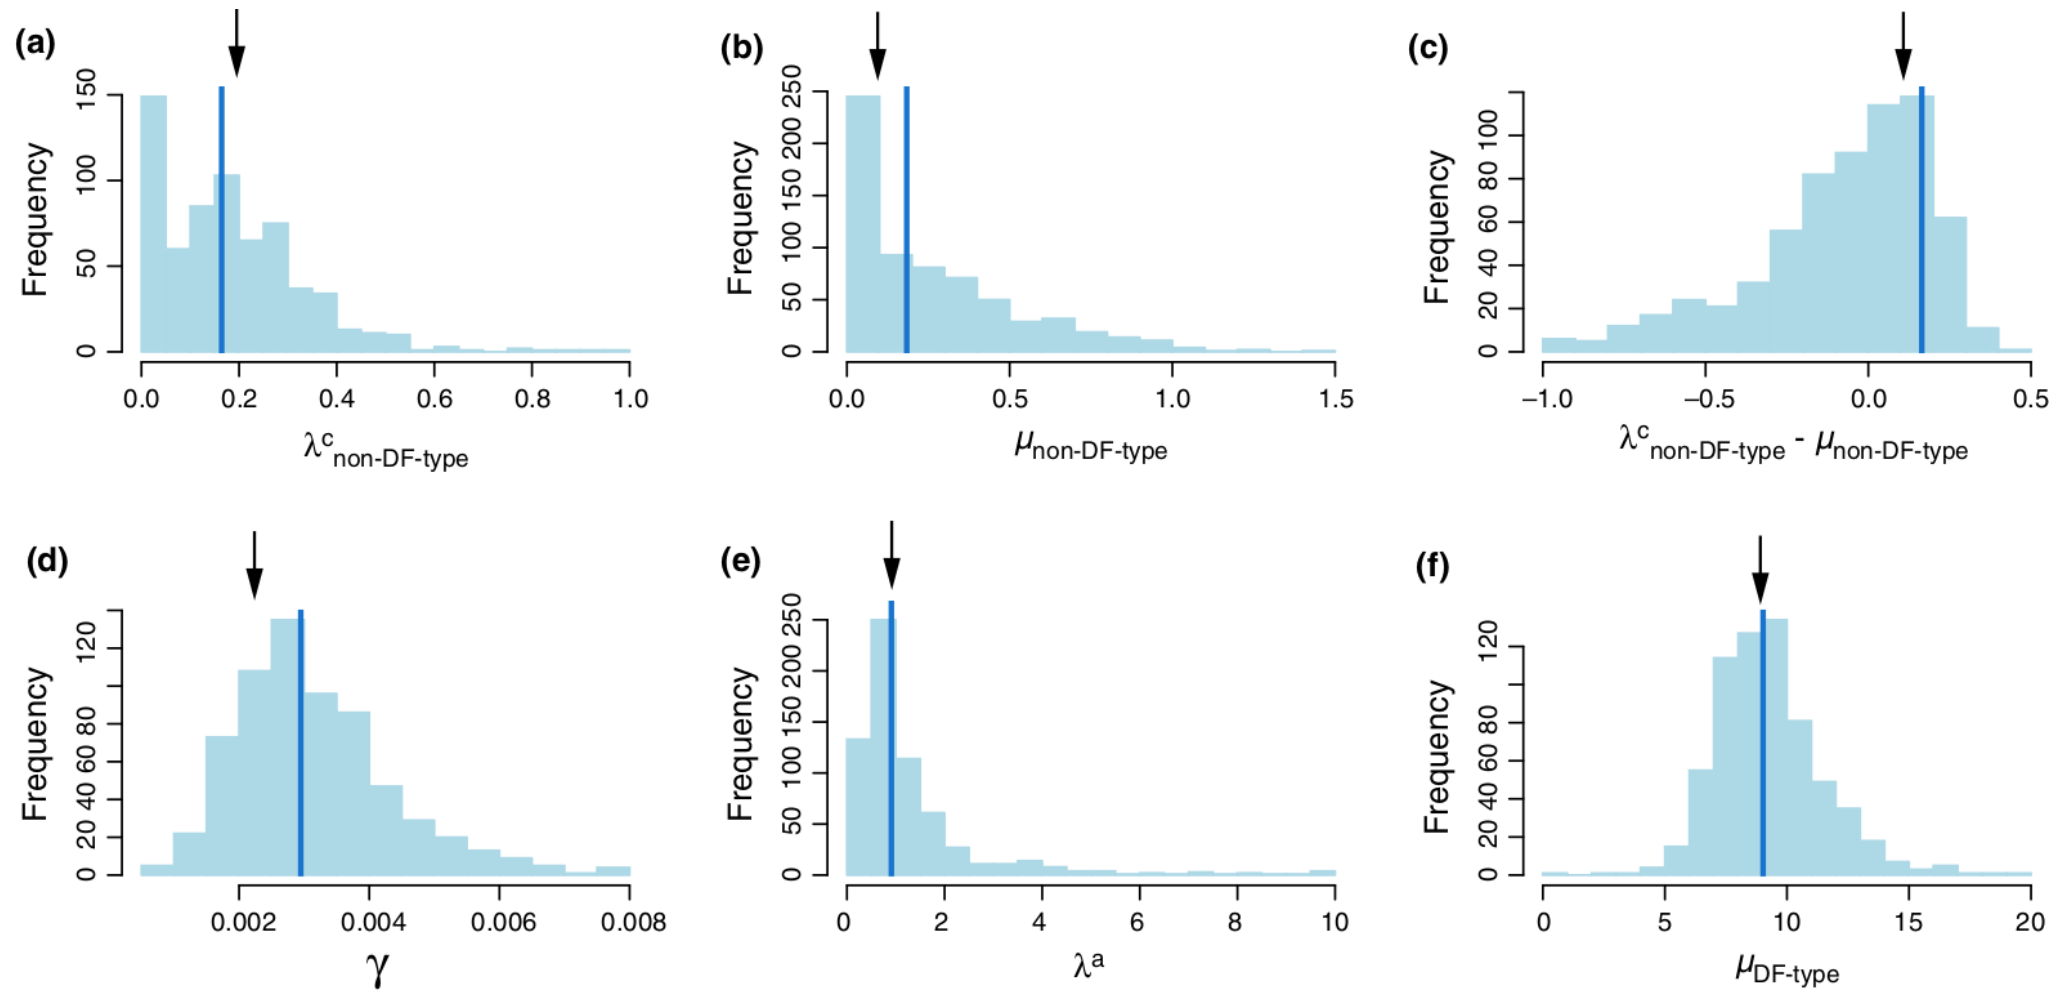

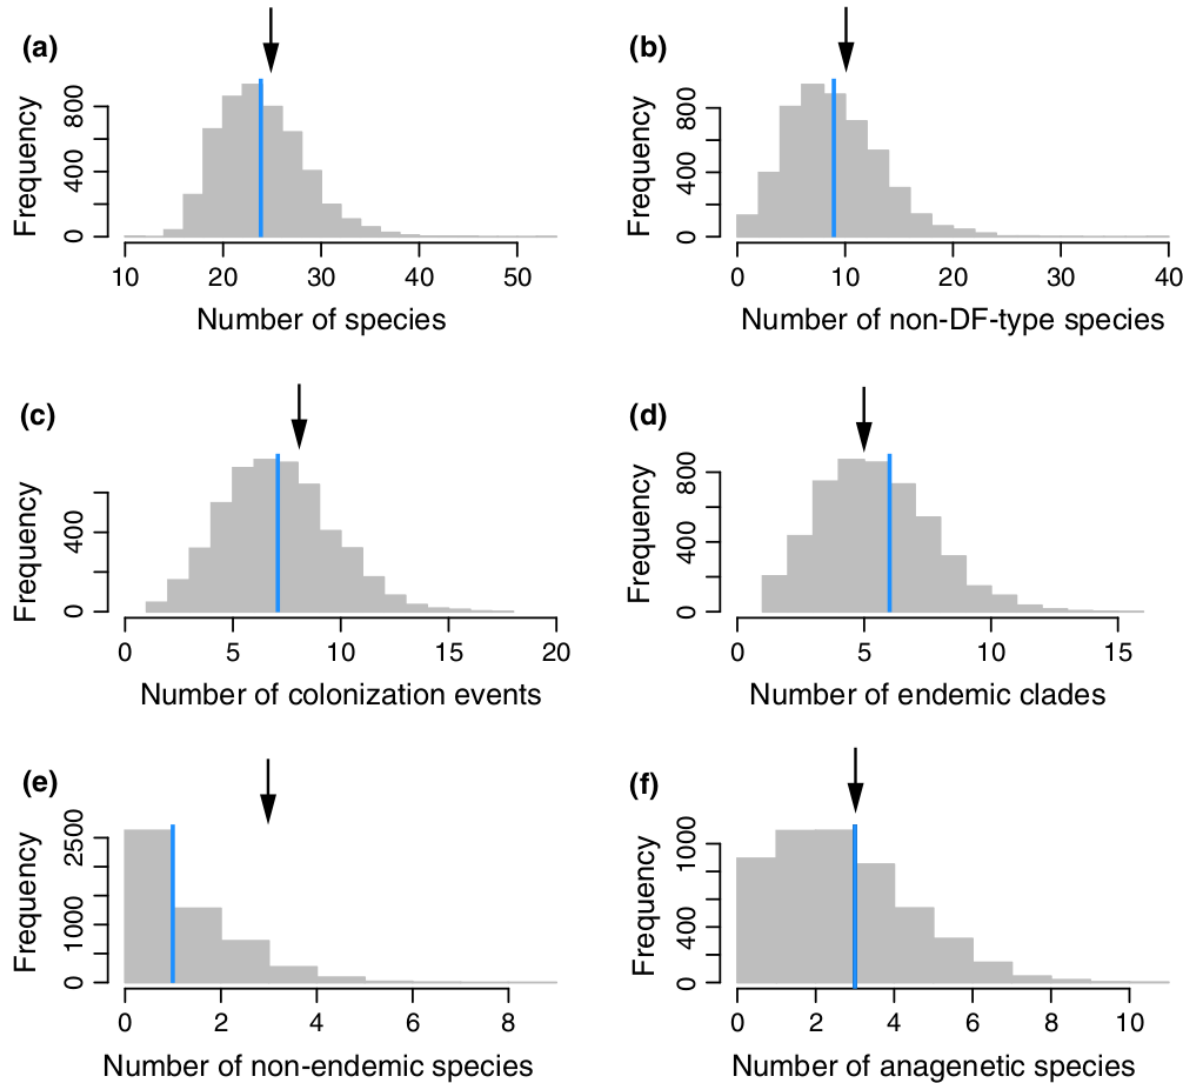

Figure 4

My claim

The Galapagos are a bad illustration of DAISIE, because (1) the final result is weak, and (2) the figures oversell the story

The result

What does the result work on?

Pretty birds, 25 species, 8 clades

What does the result work on?

25 species, 8 clades

What does the result work on?

7 clades with 10 species

1 clade with 15 species

What does the result work on?

7 clades with 10 species
1 clade with 15 species

DAISIE unifies
island biogeography
with
birth-death models

My claim

The Galapagos are a bad illustration of DAISIE, because (1) the final result is weak, and (2) the figures oversell the story

(1) there is no unification

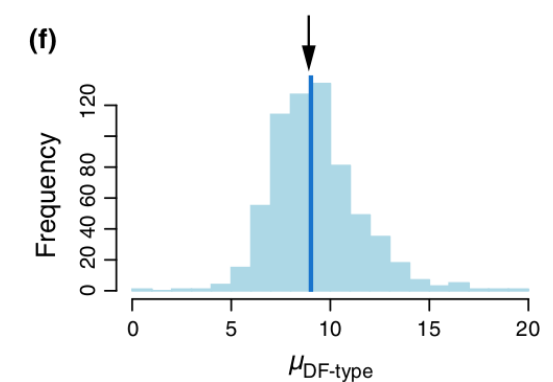

Figures, expected
